

Wearable Visual-Inertial Hand Motion Tracking Interface

- Motivation

- Limitation of vision based tracking system: occlusion, dataset-dependency.
- Limitation of wearable based tracking system: magnetic interference, lack of global position tracking, irritating calibration due to sensor bias.

- Contribution

- Developed a filtering-based state estimation algorithm by opportunistically fusing visual and inertial sensor information.
- Achieve robust hand tracking system by fusing complementary properties of both sensors which can be utilized as a Human-Robot Interaction (HRI) interface.

AI-Vision-based Robot Manipulator Development & Control

- Motivation

- Time-consuming procedure of manually manipulator trajectory assignment.
- Limitation of manual teaching of robot manipulator to grasp various types of products in Robot Production System.

- Contribution

- Developed 6-DoF collaborative robot for various purposes such as automation of Food & Beverage business or Robot Production System.
- Developed the autonomous and optimal vision calibration method enabling vision-based control of robot manipulator.
- Achieved object detection / classification through pose estimation algorithm. (Yolact, DenseFusion, EfficientPose, etc.)

Origami-inspired Multi DOF Robotic Arm

- Motivation

- Lack of unfolding mechanism of [1] limited to drone robotic arm.
- Necessity of volume-efficient and human-interactable lightweight robotic manipulator in warehouse.

- Contribution

- Designed elongated folded line to avoid over-folded state applying origami perpendicular principle.
- Accomplish folding and unfolding mechanism which is applicable to mobile robot manipulators increasing mobility with folded state and enhancing manipulability with unfolded state.

that can be folded flat. *Science Robotics*, 2018

Robot Manipulator Obstacle Avoidance Control

- Motivation

- Control of a robot manipulator with the existence of obstacles in the workspace while accomplishing desired tasks.

- Contribution

- Developed a safety control algorithm of a robot manipulator which imposes artificial potential fields around obstacle.
- Robust control while maintaining the initial configuration of the end effector to avoid singularity through null space control method.

Real-time Microbiome Diagnosis System Development

- Motivation

- High demands of microbiome dataset for on-going research studying correlation between microbiome and various diseases (e.g. diabetes, obesity, Alzheimer's).
- Necessity of relieving the discomfort of the existing fecal sampling process and improving reliability of stool sample through the automated sampling process.

- Contribution

- Developed one-click sampling mechanism achieving ease of fecal sampling process and sampling platform for building microbiome dataset.
